Your rabbit has received an immunization against Rabbit Hemorrhagic Disease Type 2, a highly-infectious viral disease that affects both wild and domestic rabbit populations. By having your rabbit immunized, you are helping to curb the spread of this devastating disease within the rabbit populations in our country. Although no vaccine offers complete protection against disease, this is the best option currently available to help prevent your pet from becoming infected with RHD. This vaccine is generally well-tolerated, but there can be minor temporary side-effects in a small percentage of patients. These include, but are not limited to:

- reduced energy
- reduced interest in food
- injection site tenderness
- soft stool
- fever
- painful muscles and joints

The majority of these signs should resolve within the first 36-48 hours, and no further action is required. However, if these signs persist or you have any concerns, you should consult with your regular veterinarian or local emergency veterinary service.

Under rare circumstances, rabbits may have more severe reactions to the vaccine. These include, but are not limited to:

- facial swelling
- respiratory difficulty
- collapse
- seizure activity
- salivation, nasal discharge, diarrhea

If your rabbit demonstrates any of these signs, you should seek emergency veterinary advice IMMEDIATELY.
